OVERVIEW
This policy documents the coverage criteria for Islet Cell Transplants. Autologous islet transplantation, performed in conjunction with pancreatectomy, is proposed to reduce the likelihood of insulin dependent diabetes. Moreover, allogeneic islet cell transplantation is being investigated as a treatment or cure for patients with type 1 diabetes.

MEDICAL CRITERIA

POLICY STATEMENT

Autologous Islet Transplantation:

BlueCHiP for Medicare and Commercial Products
Autologous pancreas islet transplantation is considered medically necessary as an adjunct to a total or near total pancreatectomy in members with chronic pancreatitis. Islet transplantation is considered not covered for BlueCHiP for Medicare and not medically necessary for Commercial products in all other situations as the evidence is insufficient to determine the effects of the technology on health outcomes.

Allogeneic Islet Transplantation:

BlueCHiP for Medicare
Allogeneic Pancreatic islet cell transplantation is covered for BlueCHiP for Medicare members only as part of an approved clinical trial. Refer to Related Policy section.

Note: Blue Cross & Blue Shield of Rhode Island (BCBSRI) must follow Centers for Medicare and Medicaid Services (CMS) guidelines, such as national coverage determinations or local coverage determinations for all BlueCHiP for Medicare policies. Therefore, BlueCHiP for Medicare policies may differ from Commercial products. In some instances, benefits for BlueCHiP for Medicare may be greater than what is allowed by the CMS.

Commercial Products
Allogeneic islet transplantation is considered not covered for the treatment of type 1 diabetes as there is no FDA approval for this indication.

COVERAGE
Benefits vary between groups/contracts. Please refer to the appropriate Evidence of Coverage or Subscriber Agreement, for applicable not medically necessary/not covered/transplant surgery/experimental/investigational benefits/coverage.
BACKGROUND
Performed in conjunction with pancreatectomy, autologous islet transplantation is proposed to reduce the likelihood of insulin-dependent diabetes. Allogeneic islet cell transplantation is also being investigated as a treatment or cure for patients with type 1 diabetes.

Chronic Pancreatitis
Primary risk factors for chronic pancreatitis include toxic-metabolic, idiopathic, genetic, autoimmune, recurrent and severe acute pancreatitis, or obstructive (the TIGAR-O classification system). Patients with chronic pancreatitis may experience intractable pain that can only be relieved with a total or near total pancreatectomy. However, the pain relief must be balanced against the certainty that the patient will be rendered an insulin-dependent diabetic.

Type 1 Diabetes
Glucose control is a challenge for individuals with type 1 diabetes. Failure to prevent disease progression can lead to long-term complications such as retinopathy, neuropathy, nephropathy, and cardiovascular disease.

ISLET TRANSPLANTATION
In autologous islet transplantation during the pancreatectomy procedure, islet cells are isolated from the resected pancreas using enzymes, and a suspension of the cells is injected into the portal vein of the patient’s liver. Once implanted, the beta cells in these islets begin to make and release insulin. Allogeneic islet transplantation potentially offers an alternative to whole-organ pancreas transplantation. In the case of allogeneic islet cell transplantation, cells are harvested from a deceased donor’s pancreas, processed, and injected into the recipient’s portal vein. Up to 3 donor pancreas transplants may be required to achieve insulin independence. However, a limitation of islet transplantation is that 2 or more donor organs are usually required for successful transplantation, although experimentation with single-donor transplantation is occurring. A pancreas that is rejected for whole-organ transplant is typically used for islet transplantation. Therefore, islet transplantation has generally been reserved for patients with frequent and severe metabolic complications who have consistently failed to achieve control with insulin-based management. Allogeneic transplantation may be performed in the radiology department.

In 2000, a modified immunosuppression regimen increased the success of allogeneic islet transplantation. This regimen is known as the “Edmonton protocol.”

The U.S. Food and Drug Administration regulates human cells and tissues intended for implantation, transplantation, or infusion through the Center for Biologies Evaluation and Research, under Code of Federal Regulation title 21, parts 1270 and 1271. Islet cells are included in these regulations.

For individuals with chronic pancreatitis who receive autologous pancreas islet transplantation, the evidence includes case series and systematic reviews. Relevant outcomes are overall survival, change in disease status, medication use and treatment-related morbidity. Autologous islet transplants are performed in the context of total or near total pancreatectomies to treat intractable pain for chronic pancreatitis. The procedure appears to significantly decrease the incidence of diabetes after total or near total pancreatectomy in patients with chronic pancreatitis. In addition, this procedure is not associated with serious complications itself and is performed in patients who are already undergoing a pancreatectomy procedure. The evidence is sufficient to determine that the technology results in a meaningful improvement in the net health outcome.

For individuals with type 1 diabetes who receive allogeneic pancreas islet transplantation, the evidence includes a randomized controlled trial, case series, and systematic reviews. Relevant outcomes are overall survival, change in disease status, medication use, resource utilization, and treatment-related morbidity. Results of a 2018 randomized trial have suggested some reduction in the number of severe hypoglycemic incidence annually, but limited follow-up and other trial limitations reduce the certainty in conclusions drawn. A wide range of insulin independence has been reported in case series. There is conflicting evidence whether allogeneic islet transplantation reduces long-term diabetic complications. Long-term comparative studies are
required to determine the effects of allogeneic islet transplantation in type 1 diabetics. The evidence is insufficient to determine the effects of the technology on health outcomes.

Medicare covers pancreatic islet transplantation in patients with type 1 diabetes participating in a clinical trial sponsored by the National Institutes of Health. Partial pancreatic tissue transplantation or islet transplantation performed outside a clinical trial are not.

**CODING**

**BlueCHIP for Medicare and Commercial Products**
The following code is covered with a diagnosis of chronic pancreatitis:

**48160** Pancreatectomy, total or subtotal, with autologous transplantation of pancreas or pancreatic islet cells

The following code is reported for pancreatic islet cell transplantation and laparoscopy:

**48999** Unlisted procedure, pancreas

**ICD-10 Diagnosis Code**

**K86.1** Other Chronic Pancreatitis

**Note:** If you are treating a BlueCHIP for Medicare member as part of a CMS approved study, please follow the procedures for correct billing and coding of services found in the policy for Clinical Trials BlueCHIP for Medicare.
